Allergy-immunology glossary

Zeinab A. El-Sayed, Hanan Abd El Lateef
Pediatric Department, Ain Shams University

Towards a clear designation of some of the terms used in allergology and immunology.

| Mast cells | Mast cells (MCs) are specifically involved in type I hypersensitivity reactions where they release their granule contents of histamine and heparin, and synthesize and secrete other mediators into the surrounding tissues. Mast cells are also involved in delayed hypersensitivity, cytotoxicity, immunoregulation and inflammation. A role is now defined for MCs in controlling dendritic cell (DC) behavior (“conditioning”) to facilitate tolerance. Under tolerant conditions, MCs mediate a marked increase in tumor necrosis factor-dependent accumulation of graft-derived DCs due to the local production of granulocyte macrophage colony-stimulating factor by MCs that induces a survival advantage of graft-derived DCs. |
| 5-hydroxytryptamine (5-HT; serotonin) | Although serotonin is not normally present, it has been demonstrated in mast cells in the stroma of carcinoid tumours and in mastocytosis. There are reports that serotonin is also increased at sites of inflammation such as in contact and atopic dermatitis; and in the blood and sputum of asthmatics. Histamine and serotonin storage in mast cells is dependent on serglycin proteoglycan. |
| Serglycin | Serglycin is a proteoglycan found in hematopoietic cells and endothelial cells. It has important functions related to formation of several types of storage granules and an important role in inflammatory reactions. In mast cells, serglycin interacts with histamine, chymase, tryptase and carboxypeptidase, in neutrophils with elastase, in cytotoxic T cells with granzyme B, in endothelial cells with tissue-type plasminogen activator and in macrophages with tumor necrosis factor-alpha. Serglycin is important for the retention of key inflammatory mediators inside storage granules and secretory vesicles. |
